

TIFF Metadata Extraction Errors

Introduction	1
Issue Risk Rating Definitions	1
Invalid DateTime separator.....	1
Invalid Strip Offset	4
Premature EOF.....	5
Tag out of sequence.....	6
Type Mismatch.....	9
Value offset not word-aligned	12

Introduction

The following is a guide to some of the metadata extraction errors you may encounter when ingesting TIFF files. When getting these errors, the first step is to ensure that the TIFF displays. If the TIFF does not display, you will have to replace the TIFF.

For general information about the TIFF file format, please refer to:

- Aware Systems TIFF FAQ: <https://www.awaresystems.be/imaging/tiff/faq.html>
- Library of Congress's TIFF sustainability page: <https://www.loc.gov/preservation/digital/formats/fdd/fdd000022.shtml>
- Just Solve the File Format Problem's TIFF page: <http://fileformats.archiveteam.org/wiki/TIFF>

Issue Risk Rating Definitions

- High –Severe issue, such as data loss or unrenderable files.
- Middle – Issues that are violations of a standard's structure.
- Low – Issues that do not violate a standard's structure.

Invalid DateTime separator

Description

DateTime refers to the date and time of image creation. In the specification, DateTime format is: "YYYY:MM:DD HH:MM:SS", with hours on a 24-hour clock, and one space character between the date and the time.

A TIFF with this issue will have an error message like this in JHOVE's output:

```

912 </repInfo>
913 <repInfo uri="4380915_AJHS_P_1_2_1_000002.tif">
914 <reportingModule release="1.5.2" date="2010-12-10">TIFF-hul</reportingModule>
915 <lastModified>2021-11-10T11:33:31-05:00</lastModified>
916 <size>30400952</size>
917 <format>TIFF</format>
918 <version>6.0</version>
919 <status>Well-Formed, but not valid</status>
920 <sigMatch>
921 <module>TIFF-hul</module>
922 </sigMatch>
923 <messages>
924 <message severity="error" id="TIFF-HUL-54">Invalid DateTime separator: 2010-10-20 07:54:12</message>
925 </messages>
926 <mimeType>image/tiff</mimeType>
927 <properties>
928 <property>
929 <name>TIFFMetadata</name>
930 <values arity="Array" type="Property">

932 <name>ByteOrder</name>
933 <values arity="Scalar" type="String">
934 <value>little-endian</value>
935 </values>
936 </property>
937 <property>
938 <name>IFDs</name>
939 <values arity="List" type="Property">

```

In this case, the DateTime string is formatted as YYYY-MM-DD HH:MM:SS, using hyphens as the date separator instead of the colons specified in the standard.

TiffDump confirms the invalid DateTime value:

```

```

Issue Risk Rating

Low: While separating the dates with anything other than colons is a violation of the standard, it does not affect the TIFF on a structural level. JHOVE deems TIFFS with this error “Well-Formed, but not valid.” Viewers can still render the TIFFS and tools can still work with the TIFFS and extract metadata.

Impact

High: In a survey of 45212 TIFFs that were flagged with metadata extraction errors, 18,054 TIFFS had this error.

Possible Fix

`fixit_tiff`, a command line tool that fixes some issues in TIFFs, can be used to fix `DateTime` errors.

The command

```
$ fixit_tiff -i original.tif -o repaired.tif
```

Creates a copy of the TIFF file with a valid `DateTime` field, with all other image data remaining untouched.

`TiffDump` confirms that `fixit_tiff` repaired the `DateTime` field while copying over all other image data:

```
$ tiffdump 4380915_AJHS_P_1_2_1_000002-repaireddatetime.tif

4380915_AJHS_P_1_2_1_000002-repaireddatetime.tif:

Possible Fix's Risks

- Corruption of image data
 - Description: Image data can become corrupted in the copy process of altering the tags.
 - Mitigation: the tool Imagemagick can calculate a hash (like a MD5) for the image data instead of the entire file using the following command:

```
$ identify -quiet -format "%#" image.tif
```

This enables us to compare the image signature of the new and original files to ensure the image data is still the same.
- Updating the wrong images in Rosetta.
 - Description: Updating files in Rosetta is a manual process. Given the scale of this issue in our preservation environment, human error in replacing one file with another's repaired copy is likely.
 - Mitigation: Quality Control checks of updated representations.
- Cost may outweigh the benefit.
 - Description: Repairing and replacing the files may take an inordinate amount of time given the Low Issue Risk Rating
 - Mitigation: Keep a record of all the files currently in the preservation system with this issue and repair them gradually overtime. Check newly created TIFFs for this error and ensure TIFF creation software is creating structurally valid files.

Invalid Strip Offset

Description

TIFF's image data is organized into blocks of data called strips and tiles. Tag 273, stripoffset, points to where each strip's starting byte is in the file. It is like a map for whatever program is reading the file. Without a correct byte offset, the decoding program cannot find, much less read the TIFF's image data.

Mickey Lindlar from TIB wrote about a similar TIFF error here:

<https://openpreservation.org/blogs/troubles-with-tiff-stripoffsets-inconsistent-with-stripbytecounts/?q=109>

Issue Risk Rating

High: In most cases, TIFFs with incorrect strip offsets cannot be rendered properly. They may render partially, or not render at all.

Impact

Low: In a survey of 45212 TIFFs that were flagged with metadata extraction errors, only 17 TIFFs had this error.

Possible Fix

There is not a programmatic solution to fix TIFFs with this error. They will have to be recreated. In some cases, this error may have occurred because of a transfer error. In this case, it may be beneficial to see if the originally created TIFF has the same checksum and/or error as the TIFF that is flagged with this error. If the original TIFF has a different checksum and has no error, a TIFF with this error can be replaced with a re-transfer of the original file instead of being recreated/rescanned.

Premature EOF

Description

EOF refers to end of file. This error occurs when a TIFF has been truncated, possibly in transfer, and all of the TIFF's data is not included in the file.

Issue Risk Rating

High: In most cases, TIFFs with premature EOF errors cannot be rendered properly. They may render partially, or not render at all.

Impact

Low: In a survey of 45212 TIFFs that were flagged with metadata extraction errors, only 40 TIFFs had this error.

Possible Fix

There is not a programmatic solution to fix TIFFs with this error. They will have to be recreated. In some cases, this error may have occurred because of a transfer error. In this instance, it may be beneficial to see if the originally created TIFF has the same checksum and/or error as the TIFF that is flagged with this error. If the original TIFF has a different checksum and has no error, a TIFF with this error can be replaced with a re-transfer of the original file instead of being recreated.

Tag out of sequence

Description

In a TIFF file, tags are information fields used to interpret image data. They include information like the width and the length of the TIFF, camera and software information, and the date the TIFF was created. The tags are arranged in a framework called an Image File Directory (IFD). The TIFF specification defines these tags and gives them a specific Code with a decimal and a hexadecimal value.

This error indicates that the tags in a TIFF file are not sorted in ascending numerical order. This is a violation of the TIFF specification, which requires that TIFF tags in an IFD must be sorted in an ascending order by their respective tag code. Using `tifftool`, a tool that views TIFF tags, we can view how the tags are sorted.

In `tifftool`, each line is a tag. The lines are arranged as so:

```
Tag name | (Tag Code) | Tag's Data Type | (Numerical Value of the
Tag's DataType) | Data Count | Data
```

In a well-formed TIFF, the `tifftool` output can look like this:

```
$ tifftool ya-rg82-f2494-001.tif
ya-rg82-f2494-001.tif:

```

In the above example, all the TIFF's tags are presented in ascending numerical order via the tag code. The tiffdump output reflects the order the TIFF tags are sequenced in the file.

In a TIFF with an out of sequence error, the tiffdump output looks like this:

```

$ tiffdump 5212791_AJHS_P_24_1_7_000092.tif
5212791_AJHS_P_24_1_7_000092.tif:

Artist (315) ASCII (2) 22<Zeutschel Omniscan 11\0>
```

In this example, all tags up to the first 305 tag are sorted in ascending order (tag 256 to 257 to 248, etc). After the first 305 tag, we see a 317 tag, followed by another 305, a 306, and a 315.

Mickey Lindlar wrote about this error here: <https://openpreservation.org/blogs/troubles-with-tiff-tag-270-out-of-sequence>

Issue Risk Rating

Medium: The specification states: The entries in an IFD must be sorted in ascending order by Tag. This error is a violation of the TIFF standard on a structural level. However, viewers are still able to render these files correctly.

In the future, it may cause issues with extracting technical metadata, or with viewers that rely on a sequential structure of tags, but that is not the case with the viewers and tools we are using in our current preservation and delivery environment. Rosetta's tools can extract the technical metadata and place it in the files DNX, as well as render the files.

Impact

High: In a survey of 45212 TIFFs that were flagged with metadata extraction errors, 35903 TIFFS had this error.

Possible Fix

Exiftool, a tool for reading, writing, and editing file metadata, can copy TIFFs' tags into a new file in the corrects sequence. The command for this would be:

```
exiftool -P -Software= -tagsfromfile @ -Software image.tif
```

A new file is created with the same filename as the original TIFF, and the original TIFF is renamed filename.tif_original. The tags' data stays the same, but they are reordered in the correct sequence. The -P flag retains the filesystem dates and times:

 5212791_AJHS_P_24_1_7_000092.tif	11/11/2021 10:15 AM	TIF File	33,277 KB
 5212791_AJHS_P_24_1_7_000092.tif_original	11/11/2021 10:15 AM	TIF_ORIGINAL File	33,277 KB

Running tiffdump shows that the tags are now in the correct sequence.

```
$ tiffdump 5212791_AJHS_P_24_1_7_000092.tif

Possible Fix's Risks

- Possible corruption of image data
 - Description: Image data can become corrupted in the copy process of altering the tags.
 - Mitigation: the tool Imagemagick can calculate a hash (like a MD5) for the image data instead of the entire file using the following command:

```
$ identify -quiet -format "%#" image.tif
```

This enables us to compare the image signature of the new and original files to ensure the image data is still the same.
- Updating the wrong images in Rosetta
 - Description: Updating files in Rosetta is a manual process. Given the scale of this issue in our preservation environment, human error in replacing one file with another's repaired copy is likely.
 - Mitigation: Quality Control checks of updated representations.
- Cost may outweigh the benefit.
 - Description: With this many TIFFS with the same error, repairing and replacing the files may take an inordinate amount of time given the Risk Rating
 - Mitigation: Keep a record of all the files currently in the preservation system with this issue and repair them gradually overtime. Check newly created TIFFs for this error and ensure TIFF creation software is creating structurally valid files.

Type Mismatch

Description

In the Image File Directory (IFD), tags' data types are listed along with their Tag IDs. A data type is a number signifying the way the tag's data is expressed. There are 12 data types that a tag can use. They are as follows:

Numerical Value	Data Type Name	Data Type Definition
1	BYTE	and 8-bit number within the range of 0 to 255,
2	ASCII	an 8-bit character string
3	SHORT	16-bit number within the range of 0 to 65535
4	LONG	32-bit number within the range of 0 to 4,294,967,295
5	RATIONAL	two 32-bit numbers within the range of 0 to 4,294,967,295
6	SBYTE	an 8-bit number withing a range from -128 to 127
7	UNDEFINE	an 8-bit byte of data of any type
8	SSHORT	16-bit number within the range of -32,768 to 32,767
9	SLONG	32-bit number within the range of -2,147,483,648 to 2,147,483,647
10	SRATIONAL	two 32-bit numbers within the range of -2,147,483,648 to 2,147,483,647
11	FLOAT	4-byte single-precision IEEE floating point value
12	DOUBLE	8-byte double-precision IEEE floating-point value

Data types 1 through 5

Every tag is assigned to a specific data type. A type mismatch error occurs if a data type does not match the tags' assigned data type.

For example, an error that reads: Type mismatch for tag 34675; expecting 7, saw 1, means that Tag 34575, the ICC Profile tag, is assigned to type 7, the UNDEFINE type. However, the tag's data type reads 1, or the BYTE type.

Running tiffdump confirms the type mismatch:

```
5515455_AJHS_I_11_3_3_000024.tif:

Issue Risk Rating

Low: In all the errors of this type in our current collection, the tag was assigned to data type 7 in the TIFF standard, but the data type in the file was either a 1 or a 2. These data types are similar. A 1 (BYTE) data type is an 8-bit number, a 2 (ASCII) is an 8-bit character, and a 7(UNDEFINE) is 8-bits of any kind of data. Since the UNDEFINE data type can be 8-bits of anything, it could be an 8-bit number or an 8-bit character. Files with this error are still viewable.

However, there may be cases where the type mismatches are dissimilar, like a Tag that is assigned to a number data type like 3 (SHORT) listing a character data type, 2 (ASCII). I have not encountered a type mismatch like this so far. We will evaluate the risk rating for dissimilar tag mismatches if we encounter an error like that in the future.

Impact

Medium: In a survey of 45212 TIFFs that were flagged with metadata extraction errors, 2440 TIFFs had this error.

Possible Fix

N/A

Action

These errors can be ignored if the data types are similar, and the TIFF displays.

Value offset not word-aligned

Description

This issue seems to be caused by an issue with Adobe Photoshop's handling of some larger EXIF files. The issue was written up by the NYU Library, Phase One, and Digital Transitions, as noted on Adobe's feedback site here: <https://web.archive.org/web/20211215191442/https://feedback-readonly.photoshop.com/conversations/photoshop/some-tiff-files-saved-from-photoshop-are-not-wellformed-in-jhove-validation/5f5f45df4b561a3d4264642d>

To quote the feedback message linked above: "If an EXIF tag is larger than four bytes, and the byte count is not a multiple of two, then it must be stored on an offset of the file with padding. This ensures the byte count is always a multiple of two. Photoshop eliminates the padding, which causes these tags to fall out of compliance with the TIFF specification."

Adobe fixed this error in February 2019

(<https://web.archive.org/web/20211215192048/https://heritage-digitaltransitions.com/adobe-fixes-bug-uncovered-by-jhove/>)

A TIFF with this error will have a message like this

```
<?xml version="1.0" encoding="UTF-8"?>
<jhove xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns="http://schema.openpreservation.org/ois/xml/ns/jhove" xsi:schemaLocation="http://schema

    <message severity="error">File not found</message>
  </messages>
</repInfo>
</jhove>
```

It appears that this error also prevents JHOVE from extracting any technical metadata.

Issue Risk Rating

Medium: While the image will still display in most viewers with this error, this is still a structural issue that prevents JHOVE from being able to extract any technical metadata, preventing the metadata from being read and indexed by our preservation system, Rosetta.

Impact

Low: In a survey of 45212 TIFFs that were flagged with metadata extraction errors, only 43 TIFFS had this error.

Possible Fix

Exiftool, a tool for reading, writing, and editing file metadata, can copy TIFFs' tags into a new file that corrects the padding issue. The command for this would be:

```
exiftool -P - Software= -tagsfromfile @ - Software image.tif
```

A new file is created with the same filename as the original TIFF, and the original TIFF is renamed filename.tif_original. The metadata stays the same, but the tags' data is padded correctly. The -P flag retains the filesystem dates and times:

Possible Fix's Risks

- Possible corruption of image data
 - Description: Image data can become corrupted in the copy process of altering the tags.
 - Mitigation: the tool Imagemagick can calculate a hash (like a MD5) for the image data instead of the entire file using the following command:

```
$ identify -quiet -format "%#" image.tif
```

This enables us to compare the image signature of the new and original files to ensure the image data is still the same.
- Updating the wrong images in Rosetta
 - Description: Updating files in Rosetta is a manual process. Human error like incorrectly replacing a file is a possibility.
 - Mitigation: Quality Control checks of updated representations.
